New study explains why superconductivity takes place in graphene. Graphene, a single sheet of carbon atoms, has many extreme electrical and mechanical properties. Two years ago, researchers showed how two sheets laid on top of each other and twisted at just the right angle can become superconducting, so that the material loses its electrical resistivity.

Experimentally, previous attempts to induce superconductivity in monolayer graphene were limited to the proximity induced superconductivity¹⁹ and in situ ARPES measurements on metal decorated graphene^{20,21} which identified features attributed to dopant-related vibrational modes²⁰ and found signatures of heavy doping as well as the appearance of an IL band in Ca-intercalated graphene bilayer (no IL band could be seen for Li intercalation).
